

ON Semiconductor®

FAN3121 / FAN3122

Single 9-A High-Speed, Low-Side Gate Driver

Features

- Industry-Standard Pin-out with Enable Input
- 4.5-V to 18-V Operating Range
- 11.4 A Peak Sink at $V_{DD} = 12\text{ V}$
- 9.7-A Sink / 7.1-A Source at $V_{OUT} = 6\text{ V}$
- Inverting Configuration (FAN3121) and Non-Inverting Configuration (FAN3122)
- Internal Resistors Turn Driver Off If No Inputs
- 23-ns / 19-ns Typical Rise/Fall Times (10 nF Load)
- 18 ns to 23 ns Typical Propagation Delay Time
- Choice of TTL or CMOS Input Thresholds
- MillerDrive™ Technology
- Available in Thermally Enhanced 3x3 mm 8-Lead MLP or 8-Lead SOIC Package (Pb-Free Finish)
- Rated from -40°C to $+125^{\circ}\text{C}$
- Automotive Qualified to AEC-Q100 (F085 Versions)

Applications

- Synchronous Rectifier Circuits
- High-Efficiency MOSFET Switching
- Switch-Mode Power Supplies
- DC-to-DC Converters
- Motor Control
- Automotive-Qualified Systems (F085 Versions)

Figure 1. FAN3121 Pin Configuration

Figure 2. FAN3122 Pin Configuration

Description

The FAN3121 and FAN3122 MOSFET drivers are designed to drive N-channel enhancement MOSFETs in low-side switching applications by providing high peak current pulses. The drivers are available with either TTL input thresholds (FAN312xT) or V_{DD} -proportional CMOS input thresholds (FAN312xC). Internal circuitry provides an under-voltage lockout function by holding the output low until the supply voltage is within the operating range.

FAN312x drivers incorporate the MillerDrive™ architecture for the final output stage. This bipolar / MOSFET combination provides the highest peak current during the Miller plateau stage of the MOSFET turn-on / turn-off process.

The FAN3121 and FAN3122 drivers implement an enable function on pin 3 (EN), previously unused in the industry-standard pin-out. The pin is internally pulled up to V_{DD} for active HIGH logic and can be left open for standard operation.

The commercial FAN3121/22 is available in a 3x3 mm 8-lead thermally-enhanced MLP package or an 8-lead SOIC package. The AEC-Q100 automotive-qualified versions are available in the 8-lead SOIC package.

Ordering Information

Part Number	Logic	Input Threshold	Package	Packing Method	Quantity per Reel
FAN3121CMPX	Inverting Channels + Enable	CMOS	3x3 mm MLP-8	Tape & Reel	3,000
FAN3121CMX			SOIC-8	Tape & Reel	2,500
FAN3121CMX-F085 ⁽¹⁾			SOIC-8	Tape & Reel	2,500
FAN3121TMPX		TTL	3x3 mm MLP-8	Tape & Reel	3,000
FAN3121TMX			SOIC-8	Tape & Reel	2,500
FAN3121TMX-F085 ⁽¹⁾			SOIC-8	Tape & Reel	2,500
FAN3122CMPX	Non-Inverting Channels + Enable	CMOS	3x3 mm MLP-8	Tape & Reel	3,000
FAN3122CMX			SOIC-8	Tape & Reel	2,500
FAN3122CMX-F085 ⁽¹⁾			SOIC-8	Tape & Reel	2,500
FAN3122TMPX		TTL	3x3 mm MLP-8	Tape & Reel	3,000
FAN3122TMX			SOIC-8	Tape & Reel	2,500
FAN3122TMX-F085 ⁽¹⁾			SOIC-8	Tape & Reel	2,500

Note:

1. Qualified to AEC-Q100.

Package Outlines

Figure 3. 3x3 mm MLP-8 (Top View)

Figure 4. SOIC-8 (Top View)

Thermal Characteristics⁽²⁾

Package	Θ_{JL} ⁽³⁾	Θ_{JT} ⁽⁴⁾	Θ_{JA} ⁽⁵⁾	Ψ_{JB} ⁽⁶⁾	Ψ_{JT} ⁽⁷⁾	Units
8-Lead 3x3 mm Molded Leadless Package (MLP)	1.2	64	42	2.8	0.7	°C/W
8-Pin Small Outline Integrated Circuit (SOIC)	38	29	87	41	2.3	°C/W

Notes:

2. Estimates derived from thermal simulation; actual values depend on the application.
3. Θ_{JL} (Θ_{JL}): Thermal resistance between the semiconductor junction and the bottom surface of all the leads (including any thermal pad) that are typically soldered to a PCB.
4. Θ_{JT} (Θ_{JT}): Thermal resistance between the semiconductor junction and the top surface of the package, assuming it is held at a uniform temperature by a top-side heatsink.
5. Θ_{JA} (Θ_{JA}): Thermal resistance between junction and ambient, dependent on the PCB design, heat sinking, and airflow. The value given is for natural convection with no heatsink, as specified in JEDEC standards JESD51-2, JESD51-5, and JESD51-7, as appropriate.
6. Ψ_{JB} (Ψ_{JB}): Thermal characterization parameter providing correlation between semiconductor junction temperature and an application circuit board reference point for the thermal environment defined in Note 5. For the MLP-8 package, the board reference is defined as the PCB copper connected to the thermal pad and protruding from either end of the package. For the SOIC-8 package, the board reference is defined as the PCB copper adjacent to pin 6.
7. Ψ_{JT} (Ψ_{JT}): Thermal characterization parameter providing correlation between the semiconductor junction temperature and the center of the top of the package for the thermal environment defined in Note 5.

Pin Definitions

FAN3121	FAN3122	Name	Description
3	3	EN	Enable Input. Pull pin LOW to inhibit driver. EN has logic thresholds for both TTL and CMOS IN thresholds.
4, 5	4, 5	GND	Ground. Common ground reference for input and output circuits.
2	2	IN	Input.
	6, 7	OUT	Gate Drive Output. Held LOW unless required input is present and V_{DD} is above the UVLO threshold.
6, 7		$\overline{\text{OUT}}$	Gate Drive Output (inverted from the input). Held LOW unless required input is present and V_{DD} is above the UVLO threshold.
1, 8	1, 8	V_{DD}	Supply Voltage. Provides power to the IC.
		P1	Thermal Pad (MLP only). Exposed metal on the bottom of the package; may be left floating or connected to GND; NOT suitable for carrying current.

Absolute Maximum Ratings

Stresses exceeding the absolute maximum ratings may damage the device. The device may not function or be operable above the recommended operating conditions and stressing the parts to these levels is not recommended. In addition, extended exposure to stresses above the recommended operating conditions may affect device reliability. The absolute maximum ratings are stress ratings only.

Symbol	Parameter	Min.	Max.	Unit
V_{DD}	V_{DD} to GND	-0.3	20.0	V
V_{EN}	EN to GND	GND - 0.3	$V_{DD} + 0.3$	V
V_{IN}	IN to GND	GND - 0.3	$V_{DD} + 0.3$	V
V_{OUT}	OUT to GND	GND - 0.3	$V_{DD} + 0.3$	V
T_L	Lead Soldering Temperature (10 Seconds)		+260	°C
T_J	Junction Temperature	-55	+150	°C
T_{STG}	Storage Temperature	-65	+150	°C

Recommended Operating Conditions

The Recommended Operating Conditions table defines the conditions for actual device operation. Recommended operating conditions are specified to ensure optimal performance to the datasheet specifications. ON Semiconductor does not recommend exceeding them or designing to Absolute Maximum Ratings.

Symbol	Parameter	Min.	Max.	Unit
V _{DD}	Supply Voltage Range	4.5	18.0	V
V _{EN}	Enable Voltage EN	0	V _{DD}	V

Notes:

14. For any inverting inputs pulled LOW, non-inverting inputs pulled HIGH, or outputs driven HIGH; static I_{DD} increases by the current flowing through the corresponding pull-up/down resistor, shown in Figure 7.
15. The initial spike in each current waveform is a measurement artifact caused by the stray inductance of the current-measurement loop.

Applications Information

The FAN3121 and FAN3122 family offers versions in either TTL or CMOS input configuration. In the FAN3121T and FAN3122T, the input thresholds meet industry-standard TTL-logic thresholds independent of the V_{DD} voltage, and there is a hysteresis voltage of approximately 0.7 V. These levels permit the inputs to be driven from a range of input logic signal levels for which a voltage over 2 V is considered logic HIGH. The driving signal for the TTL inputs should have fast rising and falling edges with a slew rate of 6 V/ μ s or faster, so the rise time from 0 to 3.3 V should be 550 ns or less.

The FAN3121 and FAN3122 output can be enabled or disabled using the EN pin with a very rapid response time. If EN is not externally connected, an internal pull-up resistor enables the driver by default. The EN pin has logic thresholds for parts with either TTL or CMOS IN thresholds.

In the FAN3121C and FAN3122C, the logic input thresholds are dependent on the V_{DD} level and, with V_{DD} of 12 V, the logic rising edge threshold is approximately 55% of V_{DD} and the input falling edge threshold is approximately 38% of V_{DD} . The CMOS input configuration offers a hysteresis voltage of approximately 17% of V_{DD} . The CMOS inputs can be used with relatively slow edges (approaching DC) if good decoupling and bypass techniques are incorporated in the system design to prevent noise from violating the input voltage hysteresis window. This allows setting precise timing intervals by fitting an R-C circuit between the controlling signal and the IN pin of the driver. The slow rising edge at the IN pin of the driver introduces a delay between the controlling signal and the OUT pin of the driver.

Static Supply Current

In the I_{DD} (static) Typical Performance Characteristics, the curves are produced with all inputs / enables floating (OUT is LOW) and indicates the lowest static I_{DD} current for the tested configuration. For other states, additional current flows through the 100 k Ω resistors on the inputs and outputs, as shown in the block diagram (see Figure 7). In these cases, the actual static I_{DD} current is the value obtained from the curves, plus this additional current.

MillerDrive™ Gate-Drive Technology

FAN312x gate drivers incorporate the MillerDrive™ architecture shown in Figure 46. For the output stage, a combination of bipolar and MOS devices provide large currents over a wide range of supply voltage and temperature variations. The bipolar devices carry the bulk of the current as OUT swings between 1/3 to 2/3 V_{DD} and the MOS devices pull the output to the HIGH or LOW rail.

The purpose of the Miller Drive™ architecture is to speed up switching by providing high current during the Miller plateau region when the gate-drain capacitance of the MOSFET is being charged or discharged as part of the turn-on / turn-off process.

For applications with zero voltage switching during the MOSFET turn-on or turn-off interval, the driver supplies high peak current for fast switching, even though the Miller plateau is not present. This situation often occurs in synchronous rectifier applications because the body diode is generally conducting before the MOSFET is switched on.

The output pin slew rate is determined by V_{DD} voltage and the load on the output. It is not user adjustable, but a series resistor can be added if a slower rise or fall time at the MOSFET gate is needed.

Figure 46. Miller Drive™ Output Architecture

Under-Voltage Lockout (UVLO)

The FAN312x startup logic is optimized to drive ground-referenced N-channel MOSFETs with an under-voltage lockout (UVLO) function to ensure that the IC starts in an orderly fashion. When V_{DD} is rising, yet below the 4.0 V operational level, this circuit holds the output low, regardless of the status of the input pins. After the part is active, the supply voltage must drop 0.25 V before the part shuts down. This hysteresis helps prevent chatter when low V_{DD} supply voltages have noise from the power switching. This configuration is not suitable for driving high-side P-channel MOSFETs because the low output voltage of the driver would turn the P-channel MOSFET on with V_{DD} below 4.0 V.

V_{DD} Bypassing and Layout Considerations

The FAN3121 and FAN3122 are available in either 8-lead SOIC or MLP packages. In either package, the V_{DD} pins 1 and 8 and the GND pins 4 and 5 should be connected together on the PCB.

In typical FAN312x gate-driver applications, high-current pulses are needed to charge and discharge the gate of a power MOSFET in time intervals of 50 ns or less. A bypass capacitor with low ESR and ESL should be connected directly between the V_{DD} and GND pins to provide these large current pulses without causing unacceptable ripple on the V_{DD} supply. To meet these requirements in a small size, a ceramic capacitor of 1 μ F or larger is typically used, with a dielectric material such as X7R, to limit the change in capacitance over the temperature and / or voltage application ranges.

Figure 47 shows the pulsed gate drive current path when the gate driver is supplying gate charge to turn the MOSFET on. The current is supplied from the local bypass capacitor C_{BYP} and flows through the driver to the MOSFET gate and to ground. To reach the high peak currents possible with the FAN312x family, the resistance and inductance in the path should be minimized. The localized C_{BYP} acts to contain the high peak current pulses within this driver-MOSFET circuit, preventing them from disturbing the sensitive analog circuitry in the PWM controller.

Figure 47. Current Path for MOSFET Turn-On

Figure 48 shows the path the current takes when the gate driver turns the MOSFET off. Ideally, the driver shunts the current directly to the source of the MOSFET in a small circuit loop. For fast turn-off times, the resistance and inductance in this path should be minimized.

Figure 48. Current Path for MOSFET Turn-Off

Operational Waveforms

At power up, the FAN3121 inverting driver shown in Figure 49 holds the output LOW until the V_{DD} voltage reaches the UVLO turn-on threshold, as indicated in Figure 50. This facilitates proper startup control of low-side N-channel MOSFETs.

Figure 49. Inverting Configuration

The OUT pulses' magnitude follows V_{DD} magnitude with the output polarity inverted from the input until steady-state V_{DD} is reached.

Figure 50. Inverting Startup Waveforms

At power up, the FAN3122 non-inverting driver, shown in Figure 51, holds the output LOW until the V_{DD} voltage reaches the UVLO turn-on threshold, as indicated in Figure 52. The OUT pulses magnitude follow V_{DD} magnitude until steady-state V_{DD} is reached.

Figure 51. Non-Inverting Driver

Figure 52. Non-Inverting Startup Waveforms

Thermal Guidelines

Gate drivers used to switch MOSFETs and IGBTs at high frequencies can dissipate significant amounts of power. It is important to determine the driver power dissipation and the resulting junction temperature in the application to ensure that the part is operating within acceptable temperature limits.

The total power dissipation in a gate driver is the sum of two components, P_{GATE} and P_{DYNAMIC} :

$$P_{\text{TOTAL}} = P_{\text{GATE}} + P_{\text{DYNAMIC}} \quad (1)$$

Gate Driving Loss: The most significant power loss results from supplying gate current (charge per unit time) to switch the load MOSFET on and off at the switching frequency. The power dissipation that results from driving a MOSFET at a specified gate-source voltage, V_{GS} , with gate charge, Q_{G} , at switching frequency, f_{SW} , is determined by:

$$P_{\text{GATE}} = Q_{\text{G}} \cdot V_{\text{GS}} \cdot f_{\text{SW}} \quad (2)$$

Dynamic Pre-drive / Shoot-through Current: A power loss resulting from internal current consumption under dynamic operating conditions, including pin pull-up / pull-down resistors, can be obtained using the “IDD (No-Load) vs. Frequency” graphs in Typical Performance Characteristics to determine the current I_{DYNAMIC} drawn from V_{DD} under actual operating conditions:

$$P_{\text{DYNAMIC}} = I_{\text{DYNAMIC}} \cdot V_{\text{DD}} \quad (3)$$

Once the power dissipated in the driver is determined, the driver junction rise with respect to circuit board can be evaluated using the following thermal equation, assuming ψ_{JB} was determined for a similar thermal design (heat sinking and air flow):

$$T_{\text{J}} = P_{\text{TOTAL}} \cdot \psi_{\text{JB}} + T_{\text{B}} \quad (4)$$

where:

T_{J} = driver junction temperature;

ψ_{JB} = (psi) thermal characterization parameter relating temperature rise to total power dissipation; and

T_{B} = board temperature in location as defined in the Thermal Characteristics table.

In a full-bridge synchronous rectifier application, shown in Figure 53, each FAN3122 drives a parallel combination of two high-current MOSFETs, (such as FDMS8660S). The typical gate charge for each SR MOSFET is 70 nC with $V_{\text{GS}} = V_{\text{DD}} = 9 \text{ V}$. At a switching frequency of 300 kHz, the total power dissipation is:

$$P_{\text{GATE}} = 2 \cdot 70 \text{ nC} \cdot 9 \text{ V} \cdot 300 \text{ kHz} = 0.378 \text{ W} \quad (5)$$

$$P_{\text{DYNAMIC}} = 2 \text{ mA} \cdot 9 \text{ V} = 18 \text{ mW} \quad (6)$$

$$P_{\text{TOTAL}} = 0.396 \text{ W} \quad (7)$$

The SOIC-8 has a junction-to-board thermal characterization parameter of $\psi_{\text{JB}} = 42^\circ\text{C/W}$. In a system application, the localized temperature around the device is a function of the layout and construction of the PCB along with airflow across the surfaces. To ensure reliable operation, the maximum junction temperature of the device must be prevented from exceeding the maximum rating of 150°C ; with 80% derating, T_{J} would be limited to 120°C . Rearranging Equation 4 determines the board temperature required to maintain the junction temperature below 120°C :

$$T_{\text{B,MAX}} = T_{\text{J}} - P_{\text{TOTAL}} \cdot \psi_{\text{JB}} \quad (8)$$

$$T_{\text{B,MAX}} = 120^\circ\text{C} - 0.396 \text{ W} \cdot 42^\circ\text{C/W} = 104^\circ\text{C} \quad (9)$$

For comparison, replace the SOIC-8 used in the previous example with the 3x3 mm MLP package with $\psi_{\text{JB}} = 2.8^\circ\text{C/W}$. The 3x3 mm MLP package can operate at a PCB temperature of 118°C , while maintaining the junction temperature below 120°C . This illustrates that the physically smaller MLP package with thermal pad offers a more conductive path to remove the heat from the driver. Consider tradeoffs between reducing overall circuit size with junction temperature reduction for increased reliability.
